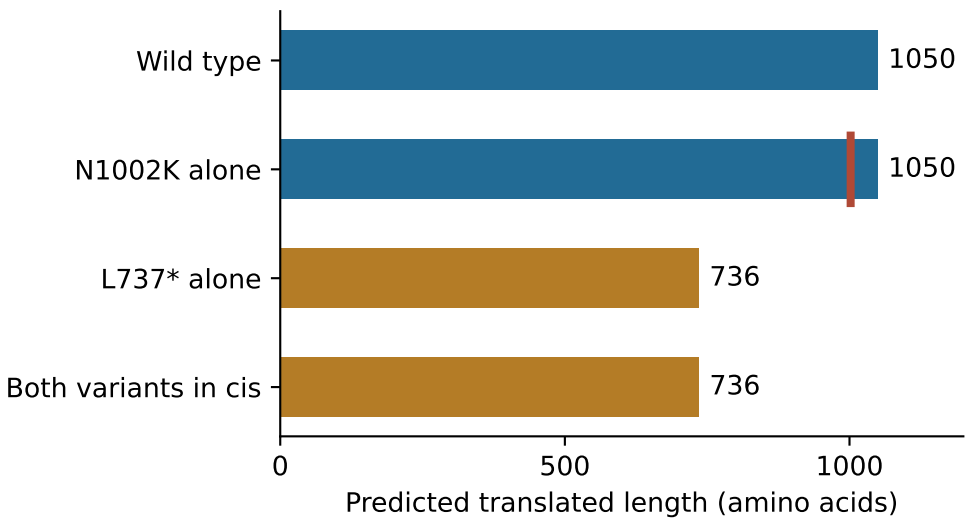
MVA: what the genome and population models can resolve

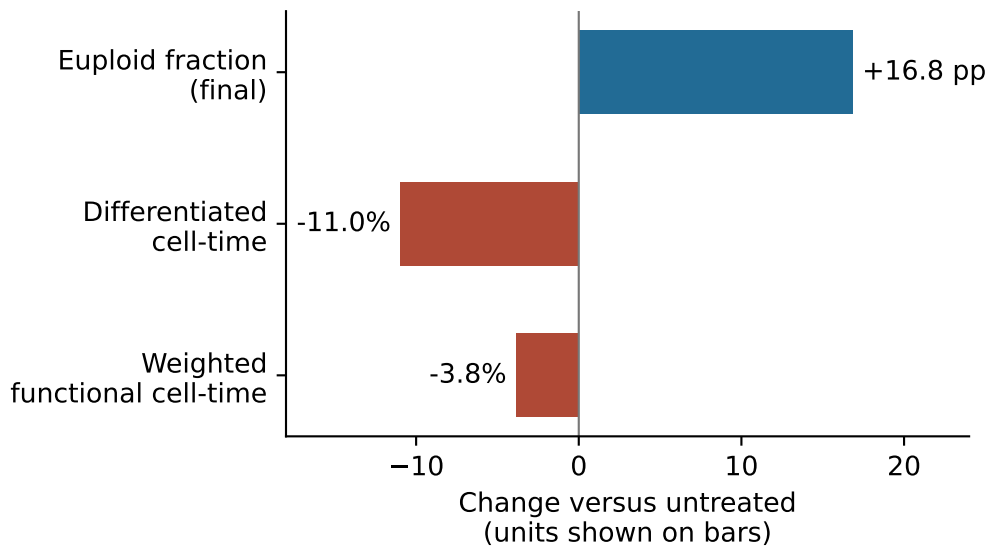
Sequence reconstruction plus assumption sensitivity — not predicted drug responses

A Sequence constrains rescue



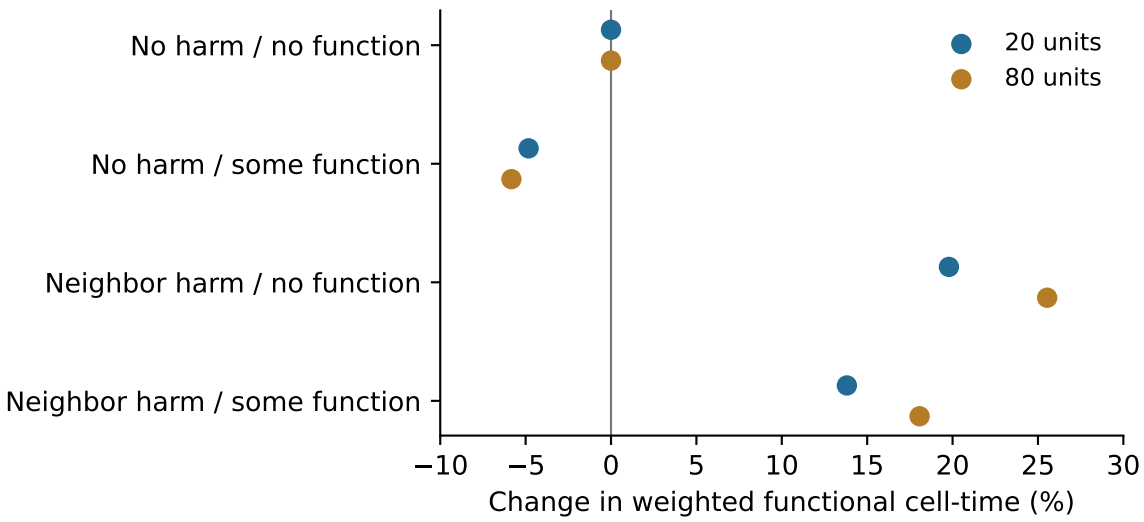
Conditional on translation; RNA and protein survival remain unknown.

B Enrichment can hide cell loss



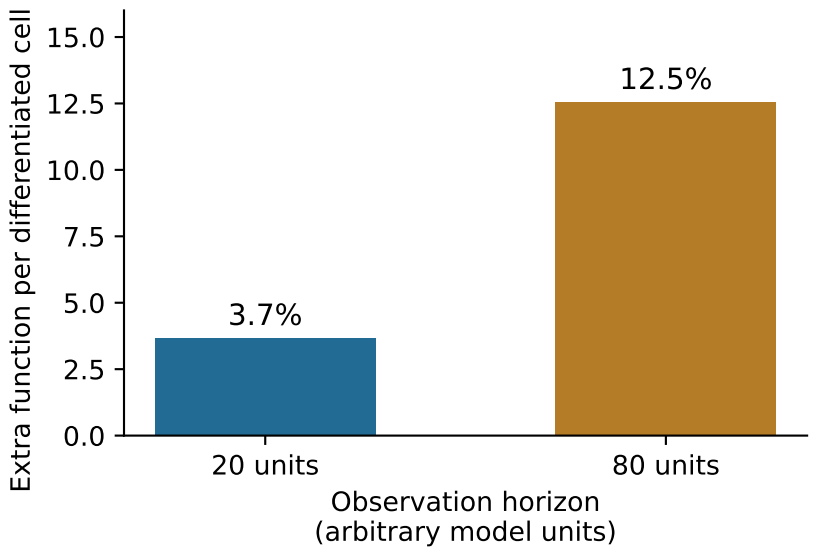
Assumed selective aneuploid killing; renewing example, 20 units.

C Senolysis can change sign



Same two pulses; no senescent niche occupancy.
"Some function" = 0.25; neighbor-harm coefficient = 1.

D Slower growth has a cost



Largest required gain after 35% slower division.
Not an estimate of mTOR-inhibitor benefit or harm.

Population rates, initial cell composition and intervention effects are assumed. No patient days or clinical effect sizes.
Panels B–C use a declared illustrative setting; panel D shows extrema in the tested grid. Full definitions and limitations: README.md.
